**GARMIII/Biological Reference Point
Pollock in SA 5&6**

R.K. Mayo, L.Col and M. Traver

"This information is distributed solely for the purpose of pre-dissemination peer review. It has not been formally disseminated by NOAA. It does not represent any final agency determination or policy."

1.0 Background

Pollock, *Pollachius virens* (L.) have traditionally been assessed as a unit stock from the Scotian Shelf (NAFO Divisions 4VWX) to Georges Bank, the Gulf of Maine and portions of the Mid-Atlantic region (Subareas 5 and 6). This stock was last assessed over its range *via* VPA at SAW 16 in 1993 (Mayo and Figuerido 1993, NEFSC 1993a, 1993b). At that time, spawning stock biomass had been declining since the mid-1980s, and was expected to reach its long-term average (144,000 mt). Fishing mortality was estimated to be 0.72 in 1992, above F20% (0.65) and well above Fmed (0.47). The stock was then considered to be fully exploited and at a medium biomass level.

The state of this stock was first evaluated *via* index assessment in 2000 (Mayo 2001). At that time, it was noted that biomass indices for the Gulf of Maine-Georges Bank portion of the stock, derived from NEFSC autumn bottom trawl surveys, had increased during the mid-1970s, declined sharply during the 1980s, but have been generally increasing since the mid-1990s. Indices derived from Canadian bottom trawl surveys, conducted on the Scotian Shelf, increased during the 1980s, but declined sharply during the early 1990s. The index assessment provided no basis with which to evaluate the state of the stock relative to the control rule as determined by the Overfishing Definition Review Panel (Anon. 1998).

In 2002, index-based biological reference points were developed for a portion of the pollock stock primarily under US management jurisdiction (Subareas 5 and 6), including a portion of eastern Georges Bank (Subdivision 5Zc) that is under Canadian management jurisdiction (NEFSC 2002). The most recent assessment of the resource inhabiting the area comprising this management unit was conducted in August, 2005 at the Second Groundfish Assessment Review Meeting (GARM II) (NEFSC 2005). At that time it was determined that the index of current biomass was greater than ½ of the Bmsy proxy reference point and that the index of current F was below the Fmsy proxy reference point (Mayo et al. 2005).

2.0 The Fishery

Since 1984, the USA fishery has been restricted to areas of the Gulf of Maine and Georges Bank west of the line delimiting the USA and Canadian fishery zones. The Canadian fishery occurs primarily on the Scotian Shelf and additional landings are obtained from Georges Bank east of the line delimiting the USA and Canadian fishery zones. This fishery on the Scotian Shelf has shifted westward over time, and the contribution to the total catch from larger, mobile gear vessels has steadily diminished since 1981.

The commercial fishery in Subareas 5&6 is dominated by United States vessels; additional catches are taken by Canada and, for a period primarily during the 1970s, by some distant water fleets. The total landings increased steadily from less than 10,000 mt during the 1960s to a maximum of over 26,000 mt in 1986 (Figure M1). Landings declined sharply during the late 1980s and have remained below 10,000 mt throughout most of the 1990s. Landings since 1994 have fluctuated between 4,420 and 9,346 mt.

Annual catches of pollock from the recreational fishery in Subareas 5&6, excluding those caught and released alive, have fluctuated between 100 and 1,000 mt. In most years the total catch remained below 400 mt.

Commercial landings: Commercial landings from the USA portion of the fishery in SA 5&6 were updated through 2006 (Table M1, Figure M1). Revised Canadian landings from Divs. 5Y and 5Z were also included through 2006. There was no need to apply the preferred allocation scheme reviewed at the GARMIII Data Meeting, October, 2007.

Commercial Biological Samples: Length and age samples continue to be collected from the USA and Canadian fisheries. For this assessment of the SA5&6 portion of the stock, length and age data have not been utilized since the 1992 assessment of the entire Divs 4VWX and SA 5&6 stock (Mayo and Figuerido 1993, NEFSC 1993a, 1993b) as noted in Section M2 below.

Commercial Discards: The extent of discarding in the commercial fishery has not been investigated to date.

Recreational Landings: USA Recreational landings are available in the MRFSS database (Table M2), and have been included in one formulation of this assessment.

3.0 Research Survey Indices

Indices of relative biomass (ln re-transformed), derived from NEFSC autumn research vessel bottom trawl surveys covering Georges Bank and the Gulf of Maine have varied considerably since 1963 (Table M2, Figure M2). Indices generally fluctuated between 2 and 5 kg per tow throughout most of the 1960s and 1970s, peaking at over 8 kg per tow during the mid-to-late 1970s, reflecting recruitment of several moderate-to strong year classes from the early 1970s. Biomass indices declined rapidly during the early 1980s, and continued to decline steadily through the early 1990s, remaining below 1 kg per tow and reaching a minimum during the mid-1990s. Since then, biomass indices from the Gulf of Maine-Georges Bank region have generally increased, reaching 1.5 kg per tow in 1999 and have recently been fluctuating between 2 and 2.5 kg/tow (Table M3, Figure M2). The most recent biomass indices declined below 1.0 in 2006 and 2007.

4.0 Assessment Results

As evident from recent trends in total landings from Subareas 5 and 6 and NEFSC autumn biomass indices calculated for the Gulf of Maine-Georges Bank region, relative Fs (landings/NEFSC autumn biomass index) peaked in the mid-to-late 1980s after which they steadily declined (Table M4 Figure M3). Biomass indices from the Gulf of Maine-Georges Bank region have been increasing throughout the late 1990s and now indicate that biomass may have returned to levels evident during the early 1980s.

Relative Exploitation Rate and Replacement Ratio Analyses

An index of relative exploitation (catch/survey biomass index) corresponding to a replacement ratio of 1.0 was developed by the Working Group on Re-Evaluation of Biological Reference Points for New England Groundfish (NEFSC 2002) for the portion of the unit stock of pollock in NAFO Subareas 5&6 based on the AIM (An Index Method) model. This model was employed again for the present assessment Autumn NEFSC survey biomass indices from the Gulf of Maine and Georges Bank region from 1963 through 2006 were used to calculate the replacement ratios, defined as the biomass index in the current year divided by the average biomass indices from the previous 5 years.

Survey biomass indices and total landings were used to compute the relative exploitation rates, defined as the catch in the current year divided by the 3 year average survey biomass index for the current year and the previous and following years. These relative exploitation rates (or relative F) may be considered a proxy for F on that portion of the pollock stock considered in this analysis. The relationship between replacement ratios and relative F was evaluated by a linear regression of the \log_e replacement ratio on \log_e relative F and the results were used to derive an estimate of relative F corresponding to a replacement ratio of 1.0. A complete description of the AIM model can be found in NEFSC (2002).

Two analyses were performed. Only commercial landings were included in the first analysis to be consistent with the analysis performed in 2002 (NEFSC 2002). The second analysis included recreational harvest estimates since 1981. Both analyses provided similar results as illustrated in Table M5. The correlation between relative F and replacement ratios for pollock were significant in both analyses ($P=0.04$).

The replacement relative F based on commercial landings alone equaled 5.637 while the estimate based on commercial and recreational landings equaled 5.758. The information provided in Table M4 and Figures M1 through M4 is based on the second analysis which included commercial and recreational harvest.

Trends in 3 year average relative F (exploitation ratio) and replacement ratios are given in Figures M3 and M4, respectively and the values are listed in Table M4. Prior to the 1980s, a high proportion of the replacement ratios equaled or exceeded 1.0 (Figure M4). During the 1980s and early 1990s, most of the replacement ratios were less than 1.0, with ratios greater than 1.0 appearing again by the late 1990s as the biomass indices began to gradually increase from the very low levels of the mid-1990s.

The information displayed in these figures also provides a means to derive a biomass index which relates to the replacement ratios. In this case, it is evident that most of the replacement ratios below 1.0 occurred during the 1980s when the biomass index was less than about 3.0 (Figure M2). It is also evident that all of the biomass indices during this period were below 2.0. This could serve as a revised B_{msy} proxy for this stock. During this period the relative Fs were also well above the relative replacement F (Figure M5). This biomass index may be considered as the biomass proxy for B_{msy} that corresponds to the relative F proxy for F_{msy} . This value remains unchanged in the present assessment compared to the value obtained in 2002 (NEFSC 2002).

5.0 Biological Reference Points

The biological reference points first developed by the Working Group on Re-Evaluation of Biological Reference Points for New England Groundfish (NEFSC 2002) are:

B _{m_{sy}}	3.00 kg/tow
F _{m_{sy}}	5.88 (Relative F)
MSY	17,640 mt

Since the relative F relates the catch directly to survey biomass, the catch corresponding to the B_{m_{sy}} proxy can be estimated by multiplying the relative F and the biomass index of B_{m_{sy}}. The following biological reference point proxies were obtained from the index-based AIM model that included commercial landings alone using the existing B_{m_{sy}} value and a revised B_{m_{sy}} value.

<u>Existing B_{m_{sy}}</u>	<u>Revised B_{m_{sy}}</u>
B _{m_{sy}} 3.00 kg/tow	B _{m_{sy}} 2.00 kg/tow
F _{m_{sy}} 5.637 (Relative F)	F _{m_{sy}} 5.637
MSY 16,911 mt	MSY 11,274 mt

The following biological reference point proxies were obtained from the index-based AIM model that included commercial and recreational landings for 2 B_{m_{sy}} values.

<u>Existing B_{m_{sy}}</u>	<u>Revised B_{m_{sy}}</u>
B _{m_{sy}} 3.00 kg/tow	B _{m_{sy}} 2.00 kg/tow
F _{m_{sy}} 5.758 (Relative F)	F _{m_{sy}} 5.758 (Relative F)
MSY 17,274 mt	MSY 11,516 mt

6.0 Summary

Since the mid-1990s, the NEFSC autumn survey biomass had been increasing towards the current 3.0 kg/tow B_{m_{sy}} proxy. However, the biomass index declined substantially in 2006 and 2007 below 1.0 kg/tow. Since 1999, the relative F has remained below the F_{m_{sy}} proxy and the replacement ratio has remained at or above 1.0

7.0 GARMIII Model Selection Meeting Panel Comments

One panel member suggested that age composition information may provide insight into recruitment pattern for this stock. While commercial catch at age has not been calculated since the early 1990s, the age composition of the survey catch/tow indices (Appendix 1) may address this comment

On first glance, it is clear from both seasons that the age structure has been truncated to a large extent, especially in the autumn survey. Large year effects tend to cloud the progression of

cohorts over time (e.g., 1985 spring, 1988 autumn

¹ NEFSC Strata 01130-01300, 01330-01340, 01360-01400.

² The "36 Yankee" trawl was used from 1970-1972, and 1982-2002; the "41 Yankee" trawl was used from 1973-1981.

No gear conversion factors are available to adjust for differences in fishing power.

³ BMV oval doors were used from 1970-1984; since 1985 Portuguese polyvalent doors have been used. No door conversion factors were applied. Surveys performed using *R/V Albatross IV* and *R/V Delaware II*; No vessel conversion factors were applied.

Table M4. Assessment measures used to evaluate the SA 5&6 component of the pollock stock
 Landings include recreational harvest.
